

What is a “register”?

It is a special location of a fixed size of bits, where binary (base 2) arithmetic takes place.

For example: Java has a 32 bit, **signed** integer register  
(1 byte = 8 bits) (32 bits = 4 bytes) (So, what’s a nybble? 4 bits)

This is an example of a 16 bit register (size = 16 bits):

R: 

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

How do we note a “register”?

R:

The values listed after the “R” are assumed to be binary (base 2),  
and **DO NOT require a subscript**.  
 (“R” implies a binary value to follow.)

You must include all leading zero’s (0) in a register as “padding”.

The decimal value 4 is illustrated in the above 16 bit register.

**How many values can we store in a register?**

$2^n$ , where  $n$  = size of the register.

Thus, a 16 bit register can store  $2^{16}$  values or 65,536 values

Hence the **range** of values 0 to 65,535 (for an unsigned register)  
or  $2^n - 1$  (the minus 1 representing the value 0)

How do we represent – 4 (negative 4)?

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

Let’s see why this is the correct answer....

# Signed Integer Registers

How do they work?  
(2's complement method)

| How many values can be stored in a 4 bit register?<br><br><b><math>2^4 = 16</math></b> | Binary #<br>(or all possible bit combinations) | Decimal Value Of Binary Number | Integers are Positive ( 0 )<br>Or<br>Negative ( 1 ) | R: <input type="text"/> <input type="text"/> <input type="text"/> <input type="text"/><br>4-bit Register "R"<br><b>Uses <i>Signed</i> integers</b><br><br>(The bit pattern represents this decimal value.) |
|--|--|--------------------------------|---|--|
| 1  |  |                                |   |  |
| 2  |  |                                |   |  |
| 3  |  |                                |   |  |
| 4  |  |                                |   |  |
| 5  |  |                                |   |  |
| 6  |  |                                |   |  |
| 7  |  |                                |   |  |
| 8  |  |                                |   |  |
| 9  |  |                                |   |  |
| 10   |  |                                |   |  |
| 11   |  |                                |   |  |
| 12   |  |                                |   |  |
| 13   |  |                                |   |  |
| 14   |  |                                |   |  |
| 15   |  |                                |   |  |
| 16   |  |                                |   |  |

Finding 2's complement representation of a binary value within a register:

1. Find the positive value
2. Flip the bits (0's become 1's, and 1's become 0's)
3. Add One (+1)
4. Result is your answer.

## More Issues With Integer Registers...

Detecting Overflow – when the sign bit of the result value is negative after adding 2 positive values.

Adding 2 positive values always results in a positive value.

Why isn't this a problem for mixed sign addition, or subtraction?

You will always remain within the range of the register!

So what is the “range” of a signed integer register?

$-2^{n-1}$  to  $+(2^{n-1} - 1)$

Let's look at the 16 bit register again...this time as a “signed integer register”:

$n=16$

- 32,768 to +32,767

Note: Range is always expressed from negative to positive value.
